

## Module 4 Cheatsheet: JavaScript Programming for Web Applications

**Class or Method Description** Example //Creates the element and text "Hello World". Appends Hello World to the HTML document. <head> An HTML DOM method <script> that after creating an function addPara() { element, you can use this var newPara = document.createElement("p"); function to place the var newText = document.createTextNode("Hello element in the appropriate appendChild() World!"); newPara.appendChild(newText); location within the document.body.appendChild(newPara); document. The element to append is the only </script> parameter. </head> <body onload="addPara()"> </body> Created by declaring the array elements in []. An array can be assigned to a variable, usually using the const Beatles = ["Ringo", "Paul", "George", "John"]; Arrays //Here Beatles[0] is "Ringo". keyword const or var. Arrays use zero based indexing to access their elements. Constructor is new Date([optional //create a new date from a string parameters]). If the var newDate = new Date("2021-1-17 13:15:30"); constructor is declared with Date() no parameters, it returns //create a new date instance representing 17 Jan 2021 current local date and time. 00:00:00 //note that the month number is zero-based New dates can be created var newDate = new Date(2021, 0, 17); by passing parameters to new Date function. //Creates the element and text "Hello World". Appends Hello World to the HTML document. <head> Takes one tag name <script> parameter and creates an function addPara() { element with that name. var newPara = document.createElement("p"); Can place the element var newText = document.createTextNode("Hello document.createElement() elsewhere on the page using World!"); newPara.appendChild(newText); functions like document.body.appendChild(newPara); insertBefore(). } appendChild(), </script> replaceChild(). </head> <body onload="addPara()"> </body> //Creates the element and text "Hello World". Appends Hello World to the HTML document. <head> <script> function addPara() { var newPara = document.createElement("p"); Takes a string as input text var newText = document.createTextNode("Hello and returns a text node with World!"); document.createTextNode() newPara.appendChild(newText); the input text. document.body.appendChild(newPara); </script> </head> <body onload="addPara()"> </body>

```
//Changes the content of the div to "Hello World!"
                                                            <div id="div1">
                                                             Hello
                                  A method of the DOM that
                                                             Hello
                                  takes an ID value parameter </div>
document.getElementByID()
                                  and returns an element that
                                  matches the id.
                                                            <script>
                                                             document.getElementById("div1").innerHTML = "Hello
                                                            World!";
                                                            </script>
                                  A method of the DOM that
                                  takes a tag name parameter
                                                            //Gets an array of all elements in a document with the
                                  and returns an array called
document.getElementsByTagName()
                                                             tag.
                                  "NodeList" that contains
                                                            var tagNameArray = document.getElementsByTagName("p");
                                  elements with the specified
                                  tag name.
                                  Writes HTML or JavaScript
                                  to a document. Note that it
                                  overwrites any other text in //Writes "Hello World" to the output stream.
document.write()
                                                            document.write("Hello World");
                                  the document so is mostly
                                  used for testing purposes
                                  only.
                                  Returns the value of the
                                                            //Removes the CSS style color blue
                                                            <div id="div1" style="color: blue"></div>
                                  specified attribute. Takes
                                                            <script>
                                  one parameter: the attribute
element.getAttribute()
                                                             var div1 =
                                  name whose value is to be
                                                            document.getelementById("div1").getAttribute("style");
                                  returned
                                                            </script>
                                                            //Changes the content of the div to "Hello World!"
                                                            <div id="div1">
                                                             Hello
                                  A property of the Element
                                                             Hello
                                  class that returns or alters
                                                            </div>
element.innerHTML()
                                  contents of an HTML
                                                            <script>
                                  element as a text string.
                                                             document.getElementById("div1").innerHTML = "Hello
                                                            World!";
                                                            </script>
                                  A property of the Element
                                  class that removes all
                                                            //Removes the CSS style color blue
                                                            <div id="div1" style="color: blue"></div>
                                  previously set inline CSS
                                                            <script>
                                  styles for a particular
element.removeAttribute()
                                                             var div1 =
                                  element. Takes one
                                                            document.getelementById("div1").getAttribute("style");
                                  parameter: the attribute
                                                            </script>
                                  name that is being removed.
                                  A property of the Element
                                  class that overwrites all
                                  previously set inline CSS
                                                            //In all elements named "theImage" sets the name of all
                                  styles for a particular
                                                            src attributes to "another.gif"
                                  element. Takes two
element.setAttribute()
                                                            document.getElementById("theImage").setAttribute("src",
                                  parameters: the attribute
                                                            "another.gif");
                                  name that is being set and
                                  the attribute value the
                                  attribute is set to.
                                  A property of the Element
                                                            //Changes the CSS style color from blue to red
                                                            <div id="div1" style="color: blue"></div>
                                  class that returns or alters
                                                            <script>
                                  inline CSS. Syntax is
element.style()
                                                             var div1 = document.getelementById("div1");
                                  element.style.propertyName div1.style.color = "red";
                                  = value
                                                            </script>
                                  Instance creates two
                                  properties about the error:
                                  message that contains
                                  description of the error and
                                  the name property identifies //Catch statement defines a block of code to be
                                                            executed if an error occurs in the try block.
                                  the type of error. Generic
                                                            catch (err) {
```

Error Objects	error plus 6 other core errors: TypeError, RangeError, URIError, EvalError, ReferenceError, SyntaxError. Error object can be extended to create custom error messages using the throw keyword.	entew new Effor ( entry variety 1 to are permitted );
History Objects	useful methods and properties that let you navigate back and forth through the user's history and manipulate the contents of the history stack.	6 //Go back two pages if the history exists in the history list. history.go(-2);
insertBefore()	An HTML DOM method that, after creating an element, places a child element in the appropriate location before an existing child. The method takes two parameters, the node object to be inserted and the existing node to insert before.	<pre>//Creates a new <li> element and places it in the elementList before the first child of <ul> let newLI = document.createElement("li"); newLI.innerText = "new Element"; let elementList = document.getElementById("thisList"); elementList.insertBefore(newLI, elementList.childNodes[0]);</ul></li></pre>
Location Objects	The location object is part of the window object and contains information about the current URL.	<pre>//Returns the hostname property let myhost = location.hostname; newLI.innerText = "new Element";</pre>
Navigator Objects	The navigator object is part of the window object class in the DOM that represents the client Internet browser, also called the user agent. There is no standard for this object so what it returns differs from browser to browser.	<pre>//Retrieves the name of the browser var browsername = navigator.appName:</pre>
onload()	A DOM event that starts a method when a page is loaded.	<pre>//Executes myFunction after MyHTMLPage has been loaded document.getElementById("MyHTMLPage").onload = function () {myFunction};</pre>
replaceChild()	After creating an element, this function replaces a child node with a new node	<pre>//Creates a new node and replaces the second element in "thisList" with the word "blue" let secondBullet = document.createTextNode("blue"); var myList = document.getElementById("thisList").childNodes[1]; myList.replaceChild(secondBullet, myList.childNodes[1]);</pre>
Screen Objects	The screen object is part of the window object class in the DOM that can be used to return properties about the user's screen.	<pre>//Returns the height and width of the user's screen var height=screen.height; var width=screen.width;</pre>
Window Obio La	The DOM window object is at the top of the DOM hierarchy and serves as the global object. Everything in the DOM takes place in a	
Window Objects	the DOM takes place in a	,, a non alondol mindom mion one operation one

window. The window object controls the environment that contains the document.

Opens a new window. The

window.open("http://www.w3schools.com");

window.open()

window.scrollTo()

Wrapper Objects

first parameter is a path, a URL, or an empty string, and optional parameters include the window name. features such as the placement of the window or the dimensions, and a Boolean replace value. The feature parameter is a comma separated string of name-value pairs and the replace parameter is an optional Boolean. This parameter has been deprecated so modern browsers may not support it. This method returns a reference to the new window object. Scrolls to a particular place

in a window. Parameters include the x-coordinate and the y-coordinate which is the upper-most pixel. Primitive types can be converted to objects using wrapper objects. They are the same name as the primitive except they start with uppercase letter. The

typeof keyword returns a

string indicating the data

type of the operand.

//Opens a new window that opens the IBM home page and has a width of 600 and a height of 800) let thisWindow = window.open("http://www.ibm.com", "myWindow", "width"=600, "height"=800);

//Scrolls the window to the pixel located at the which is the left-most pixel window.scrollTo(20, 200); coordinate (20, 200) //Enables the use of properties and methods of the String class such as the property n.length let n = new String ("abc"); //Returns string typeof "abc"; //Returns object

typeof new String("abc");
